

EXPERIMENT-12

Aim: Verify the functionality of water flow sensor.

Appartus: Arduino UNO Board, YF-S201, water flow sensor connecting wires, USB cable.

Theory :

A water flow sensor is an electronic device that is used to measure water flow rate.

Furthermore, the flow rate means the volume of water passes through a sensor per unit of time. There are many types of water flow rate measurement sensors available in the market such as YF-B1, YF-B2, YF-B3, YF-B4, YF-B5, YF-B6, ~~AI&2~~, ~~AI&4~~, ~~AI&8~~ and YF-S201.

All these sensors are almost the same except for the difference in flow rate range, operating voltage range, length, size, and material used. But their working principle and the procedure to interface with micro-controllers such as Arduino remains the same.

Performance Result:

EXPERIMENT-13

```

conclusion:

The water flow sensor with Arduino UNO successfully measure and verifies water flow by generating pulses proportional to the flow rate, making it useful of monitoring and control in fluid systems
