

Annexure No.:

EXPERIMENT - 02

Aim: Identification, symbolic representation and testing of various electronics components.

Apparatus: Resistor, 1-Diode, capacitor, LED, multimeter.

Theory:

A diode is a semiconductor device that allows current to flow in only one direction [-] when it has two terminals anode [+] and Cathode [-] when forward biased. it conducts current, when reverse biased, it blocks current.

Diodes are mainly used for rectification [converting AC to DC] and are also used in applications like voltage and current regulation LED and electronics circuits due to their one way current property.

Procedure :— Diode testing :

Step - 1: keep multimeter

2: Connect multimeter positive terminal to diode

3: connect common terminal of multimeter to cathode terminal.

4: Multimeter shows some readings then diode is in good working condition

Annexure No.:

Transistor Testing :

Continuity check :

- [i] It is used to find connection between components of PCB.
- [ii] keep multimeter knob at play and diode symbol.
- [iii] If we hear (beep) sound from multimeter it indicates connections are properly b/vv 2 components on PCB.

Transistor :

connect the terminal negative or common to collector to measure the Resistance the resistance it should read open circuit it is open circuit.

Conclusion:

by performing above experiment we can conclude that identification symbolic representation and testing of semiconductor diode, zener diode, LED, transistor VB are studied using digital multimeter.
